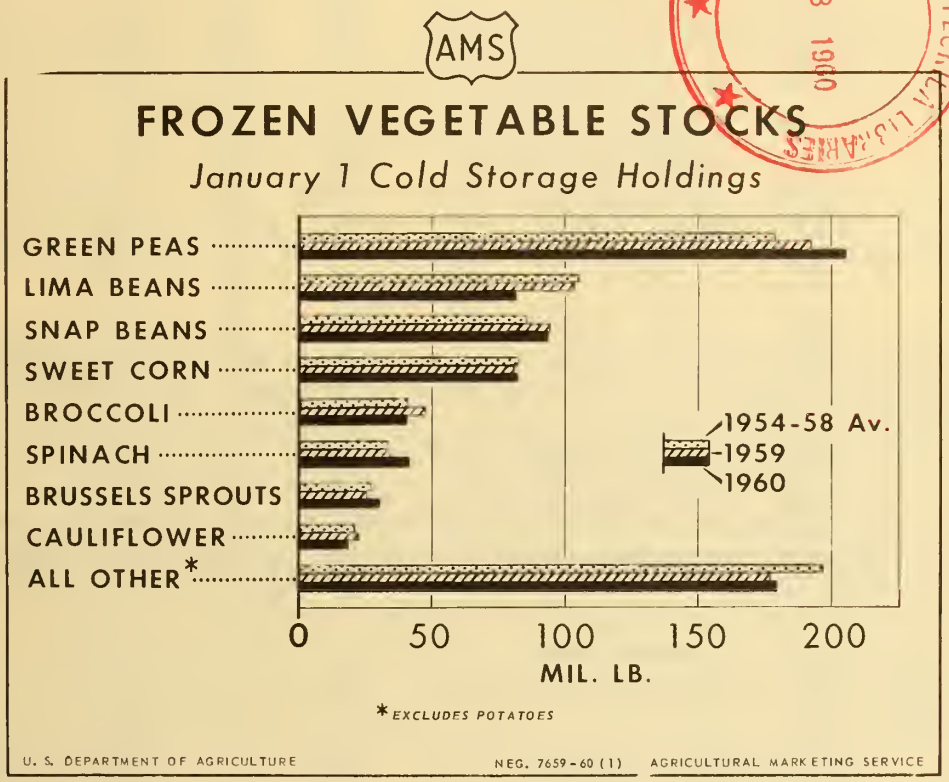
The VEGETABLE SITUATION

TVS-135

UNIVERSITY OF FLORIDA
FEB 1960
LIBRARIES



Total stocks of frozen vegetables on January 1 were about the same as a year earlier, but almost a tenth above the 1954-58 average. Supplies of green peas and spinach were relatively heavy, while holdings of lima beans were light.

Consumption of frozen vegetables in the first half of 1960 probably will be a little larger than in the first half of 1959. Retail prices of most items during the next 4 to 6 months probably will average a little above those of a year earlier.

SUMMARY

On January 1 aggregate production of 20 commercial fresh vegetables for winter-season harvest was expected to be about 9 percent larger than last winter, and 7 percent above the 1949-58 average. However, near freezing to below freezing temperatures in Florida from January 20 to 25 resulted in heavy damage and serious loss of tender vegetables, most of which are produced in that State. Early reports indicate heavy loss of snap beans, sweet corn, cucumbers, tomatoes and squash, and more moderate damage to green peppers. The prospective supply situation is much more favorable for the more hardy crops, a large portion of which is produced in California, Arizona and Texas. Also Florida acreage of such crops apparently came through the freeze with little damage. Among hardier crops, total U.S. tonnages of celery, kale and spinach are expected to be down materially as a result of less acreage. But materially larger tonnages are likely for cabbage, carrots, lettuce, broccoli, and cauliflower, and a more moderate increase for beets.

Remaining supplies of canned vegetables appear to be a little smaller than the heavy supplies of a year ago, but at least moderately above the 1949-58 average. Except for sauerkraut, all major canned items appear to be in ample supply. January 1 stocks of frozen vegetables were about the same as those of a year earlier.

Movement of frozen vegetables into consumption during the first half of 1960 is expected to be moderately larger than in the first half of 1959, and movement of canned items probably slightly larger. Stocks of both canned and frozen items at the end of the current season are expected to be at least moderately smaller than the heavy stocks at the beginning of the season.

Supplies of potatoes available for distribution into early spring will be substantially smaller than the heavy supplies of a year earlier. January 1 stocks of fall-crop potatoes, at 97.5 million hundredweight, are down 10 percent from the high level of a year ago. Estimated winter production is also down substantially. The situation appears to be one of adequate, but not burdensome supplies. Into early spring, prices of both storage potatoes and new crop potatoes are expected to average materially above the low levels of a year earlier.

Reports indicate that growers plan to plant moderately more acreage this year than last to both early and late spring potatoes. Given near average weather for the rest of the season, production for spring harvest is likely to be moderately larger than last year. Prices in early spring probably will average substantially above those of early spring 1959. But the sharp advance of last spring is not likely to be repeated, and prices in late spring probably will average below the high levels of a year earlier.

The 1959 crop of sweetpotatoes was up 8 percent from 1958. Remaining supplies probably are at least moderately larger than a year ago. Prices to growers are likely to remain substantially below those of last season.

Production of colored classes of dry edible beans was much smaller in 1959 than in 1958. As a result, these classes are in tight supply, and prices high. Supply of white beans as a group was considerably larger than a year earlier. However, both domestic and export demand for white beans has been strong, with exports in the early part of the season unusually heavy. During the next 4 to 6 months prices to growers for colored beans are expected to remain well above those of a year earlier. Prices of white classes are expected to remain above support levels, though prices of pea beans, largest of the white classes, are likely to average below those of last season.

Supplies of dry field peas are much larger than the relatively light supplies of a year ago. Both export and domestic demand has been good so far this season, with exports running well ahead of last season. Domestic use is expected to exceed that of last season, but exports for the season as a whole may be down from the high levels of last season. During the next 4 to 6 months prices of green kinds probably will continue below those of a year earlier, but white and wrinkled kinds may remain higher.

COMMERCIAL VEGETABLES FOR FRESH MARKET

Production and Value of Fresh Vegetables in 1959 Near That of 1958; Melon Production Lower, Value Up

Acreage of vegetables harvested for fresh market sale in 1959, excluding melons, was 2 percent smaller than in 1958. Tonnage was about the same as a year earlier, and slightly larger than the 1949-57 average. Among the 10 items with the largest volume, production of cabbage, carrots, cauliflower

and cucumbers was substantially smaller than a year earlier, and snap beans slightly smaller. But output of celery and dry onions was materially larger than in 1958, tomatoes moderately larger, and lettuce and sweet corn slightly larger. Acreage of both cantaloups and watermelons was down from a year earlier. Production of cantaloups was fractionally larger, but production of watermelons was down almost a fifth.

Demand for fresh vegetables remained strong in 1959. Among the 10 leading vegetables from the standpoint of volume, prices averaged significantly lower for only two items -- celery and dry onions. Prices received by growers in 1959 were close to those of a year earlier for cauliflower and lettuce, and moderately to substantially higher for snap beans, cabbage, carrots, cucumbers, sweet corn and tomatoes. Aggregate value of commercial vegetables, excluding melons, for fresh market in principal producing States, amounted to about $681 million in 1957, compared with about $675 million in 1958.

Prices of cantaloups were materially above those of 1958, and watermelons were much above the low levels of a year earlier. Aggregate value of melons amounted to about $111 million in 1959, well over the $87 million of 1958.

Low Temperatures in Florida Hit Winter Vegetables

January 1 estimates of the Crop Reporting Board indicated a production of winter vegetables about 9 percent larger than last winter and 7 percent above the 1949-58 average. However, tender crops, grown largely in Florida, suffered heavy damage and serious loss as a result of near freezing to below freezing temperatures from January 20 to 25. Early reports indicate heavy loss of snap beans, sweet corn, cucumbers, tomatoes and squash, and more moderate damage to green peppers. Hardy crops, a large portion of which is grown in California, Arizona and Texas, are in a more favorable supply situation. Also, acreages of such crops in Florida came through the freeze with only light damage. Among the more important crops, production of sweet corn, tomatoes and green peppers is expected to be much smaller than last winter, and production of celery and spinach at least moderately smaller. But output of winter-season cabbage, carrots, cauliflower and lettuce is expected to be substantially larger than last winter. Among other vegetables, smaller supplies are in prospect for kale, and larger supplies for beets and broccoli.

Domestic production of tender winter vegetables, particularly tomatoes, cucumbers and peppers, will as usual be supplemented by imports from Mexico and Cuba. Early reports indicated that production of winter vegetables in Mexico would be larger than last winter. But recent heavy rains and floods have caused considerable damage and loss. However, with tight domestic supplies of tender vegetables, imports from Mexico may be as large as a year earlier. Production and imports from Cuba are expected to be below last winter.

Prospects For Leading Crops

Cabbage. Supplies of cabbage available this winter are likely to be materially larger than both last winter and the 1949-58 average. January 1 stocks of fall-crop cabbage were relatively light, but production for winter harvest is expected to be substantially above both last winter and average.

Growers of early fall cabbage, who received low prices for the 1958 crop, cut acreage moderately in 1959. Hot, dry weather, particularly in the East, was less favorable than a year earlier, and yield per acre was much lower. Total early fall production, for fresh market and processing, was down a fourth from 1958. Acreage in Upstate New York was moderately smaller than in 1958, and yield per acre was down sharply. As a result, harvested tonnage of Danish cabbage was a fourth smaller in 1959. Much of the crop was not of suitable quality for storage. Also, small overall supplies of cabbage and high prices this fall encouraged sales. This left January 1 stocks in producing areas of only 195,000 hundredweight, compared with 712,000 a year earlier and the 9-year average of 530,000. With only light supplies remaining, prices of storage cabbage are likely to continue relatively high. Most of the small late crop production in Virginia, North Carolina, and South Carolina moved to market before January 1.

However, the great bulk of cabbage available in the first quarter of the year will come from winter production. January 1 reports indicate that output of cabbage for winter-season harvest is expected to be about a fourth larger than last winter. Acreage is up in all States except Arizona, which reports no change, and prospective yields are also higher in Texas and may be higher in Florida. Indicated production is up sharply in Texas and California. Production in Florida is also expected to be larger than a year ago, though low temperatures from January 20 to 25 retarded the crop and lowered quality. Arizona, of minor importance in the total picture, reports a smaller crop.

During the rest of the season, cabbage is expected to benefit from curtailed supplies of several other fresh vegetables. Despite the substantially larger supplies in prospect, prices to growers during the next 6 to 8 weeks may average close to those of a year earlier.

Early December reports indicate a slight reduction from 1959 in prospective acreage of cabbage for early spring harvest. But near normal yields might result in a little larger production than last year, when yields in most States were below average.

Celery. Supplies of celery are materially smaller this winter than last, but almost a sixth above the 1949-58 average. Acreage in all States is smaller than last winter. Most of the reduction in expected output is in Florida where acreage was down 17 percent and yield prospects have been cut by low temperatures. Prospective output in California is close to that of last winter, while the less important Arizona crop is down substantially.

Marketings of celery in early January were somewhat smaller than for the comparable weeks of 1959 and f.o.b. prices averaged higher. Supplies

available during the rest of the season are expected to remain materially below those of last winter. Prices to growers in the next 6 to 8 weeks are expected to average substantially above the low levels of a year earlier.

Lettuce. Production of lettuce for winter-season harvest promises to be materially larger than both last year and the 1949-58 average. Acreage was up in all States except Florida which reported no change, and yield per acre is up in Florida and Texas. Total prospective production is almost a tenth larger than both last winter and average. About three-fourths of the total winter production is in California, mostly in the Imperial Valley. Supplies are heavy, but growers and shippers in the Valley are operating under a State marketing agreement and order program, similar to the one in effect last winter. Purpose of the order in California is to limit shipments to the more desirable grades and sizes, promote orderly marketing and increase returns to growers. Also, lettuce is expected to benefit considerably from the tight supply situation for a number of other salad items. Rains in late December caused some lowering of quality, and low temperatures and heavy frosts on January 1-3 reduced head sizes and slowed maturity.

Onions. Supplies of onions available for distribution during the next 6 to 8 weeks are more than a fourth larger than a year earlier and a sixth larger than the 1950-58 average. The late summer crop, a large part of which goes into storage, was more than a tenth larger than both 1958 and the 10-year average. Disappearance of onions to January 1 was considerably larger than a year ago and the largest in the past decade. Reported losses to January 1 were heavier than last year in the important States of New York, Minnesota, Idaho-Eastern Oregon, Colorado and Western Oregon. Nevertheless, remaining supplies of sound onions held by growers and dealers on January 1 amounted to 5.7 million hundredweight, compared with 4.4 million a year earlier and the 9-year average of 4.8 million. Cold storage stocks were down in 1959, but holdings in common storage, more than 90 percent of the total, were up sharply. Biggest increase over January 1, 1959 was in the Eastern States, where total holdings were up 54 percent. Stocks were up 26 percent over 1959 in the Western States and 17 percent in the Central States. However, holdings in the Central States were slightly below average.

Production estimates are not yet available for the early spring crop in Texas. Early estimates indicate 28,500 acres for harvest in 1960, 14 percent less than last year. But most of the reduction this year is in dry land areas where yields are relatively low. Also, early plantings have made better progress and overall yield prospects are better than last year when the crop was seriously delayed and yields lowered by adverse weather. Early acreage is expected to furnish light shipments starting about mid-February, several weeks ahead of last year.

Larger January 1 supplies of storage onions, and the prospect of earlier volume movement from the early spring crop indicate large market supplies of onions during the next few weeks compared with the light supplies

of a year earlier. Both prices to growers and retail prices of onions during the next 6 to 8 weeks are expected to average much below the high levels of a year earlier.

Intentions reports indicate that growers plan to plant 6 percent less acreage of onions for late spring harvest than last year, and a fifth less than the 1949-58 average. In California, which accounts for almost two-thirds of the production, acreage is up 19 percent over 1959. But substantial reductions are in prospect in Arizona, Texas, North Carolina and Georgia. However, because of the larger acreage in California, where yield is relatively high, overall yield for the late spring crop may be moderately higher than last year. Yields near the 1956-59 average, by States, on the indicated acreage would result in a 1960 production near that of last year and much above the 10-year average. Production at this level probably would result in some marketing difficulties and below average prices.

Carrots. Early estimates indicate a production of carrots for winter harvest of 5.3 million hundredweight. This is about a fourth larger than last year and 8 percent above the 1949-58 average. Acreage and prospective production are up substantially in Texas, California and Arizona. Hot weather in Texas in September and early October and heavy rains in mid-October damaged early plantings and resulted in considerable replanting.

Weekly unloads of carrots in the 38 reporting cities during December were larger than a year ago, with the bulk of shipments from California and Texas. However, prices to growers averaged materially above the low levels of a year earlier. Unloads in the early weeks of January were substantially larger than those in comparable weeks of 1959, and f.o.b. prices averaged materially lower. Indications are that the harvest pattern in Texas may be more nearly normal than last year, when harvest was seriously delayed, with heavy marketings late in the season. However, with larger overall supplies available, prices for the remainder of the winter season probably will remain relatively low.

Tomatoes. The Florida crop of tomatoes for winter-season harvest is expected to be much smaller than both last year and the 1949-58 average. Acreage was down 30 percent from 1959, and the crop suffered heavy losses from low temperatures on January 20 to 25. Also, fewer tomatoes than last season are available for import from Cuba. Early reports indicated that more than last year might be available for import from the West Coast of Mexico. Heavy rains and floods in early January caused considerable damage. Nevertheless, with a larger acreage of staked tomatoes, which have a higher yield, tonnage available for export may be as large as a year earlier. In any event, total supplies for U. S. consumption are expected to be materially smaller this winter than last.

The next issue of the Vegetable Situation is scheduled for release on April 29, 1960.

Watermelons. Early reports indicate that growers plan to have about the same acreage of watermelons for late spring harvest this year as last. Prospective 1960 acreage in Florida is the same as in 1959, and in California 1-percent larger. Some early plantings in South Florida were destroyed by low temperatures in late January, and considerable replanting will be necessary. Yields near the 1955-59 average, by States, would result in production in Florida substantially larger than last spring, but at least moderately below the 1949-58 average; production in California would be smaller than last year, but probably above average. If output reaches these levels, prices to growers in California probably would average at least as high as the near average prices of last season; but prices to Florida growers probably would average materially below last season.

VEGETABLES FOR COMMERCIAL PROCESSING

1959 Acreage, Production, and Value of Vegetables for Processing Down From A Year Earlier

Harvested acreage of 10 crops for commercial processing was about 4 percent smaller in 1959 than in 1958, and about a tenth below the 1948-57 average. The 1959 growing season was generally favorable and, except for snap beans and cabbage, yields approached or exceeded the high levels of the previous season. However, because of acreage reductions in a number of crops, and the sharp cut in tomato acreage, a crop with relatively high yields per acre, overall production was down 8 percent from the high level of 1958. In addition to a much smaller production of tomatoes, tonnages of lima beans, beets, green peas, and cucumbers for pickles were down as a result of acreage cuts. Also, output of cabbage for kraut was down sharply as a result of 13 percent less acreage and a much lower yield. Sweet corn and spinach were the only important crops to show substantial increases in tonnage. Production of asparagus was up moderately, and snap beans up slightly.

Prices for cabbage for kraut, in 1959 were substantially higher than in 1958, for asparagus, beets and sweet corn a little higher, and for tomatoes the same as in 1958. Higher prices for some items were about offset by slightly to moderately lower prices for lima beans, snap beans, green peas, spinach and cucumbers for pickles. Total value of 10 important processing crops in 1959 amounted to a little more than $259 million, about 7 percent less than the value of the 1958 crops.

Prospects for 1960

Supplies of canned vegetables appear to be a little smaller than the heavy supplies of a year ago, but materially larger than the 1949-58 average. Holdings of frozen vegetables are about in line with a year ago. Stocks of both canned and frozen items at the end of the current season probably will be at least moderately smaller than the relatively heavy stocks of a year earlier.

The movement and market tone of processed vegetables during the next 2 or 3 months will have some influence on processor operations in 1960. But overall supplies of processed vegetables in the last 3 seasons have been generally heavy, and prices paid to both canners and freezers for a number of major items have been low relative to their raw product, labor and material costs. To avoid the likelihood of burdensome supplies and low prices, processors should keep the 1960 pack in line with anticipated market requirements. The Departments 1960 acreage-marketing guide for commercial vegetables for processing, which gives detailed recommendations for individual items, is being prepared for release in early February. Copies may be obtained from the Agricultural Marketing Service.

CANNED VEGETABLES

Production of vegetables for commercial processing and incomplete pack data indicate that the total pack of canned vegetables in 1959 was somewhat larger than the 1949-57 average, but moderately to substantially smaller than the 1958 pack. Among the more important items, the pack of sweet corn was much larger than the light pack of a year earlier. But the packs of green peas, tomatoes, and tomato juice were materially smaller than the heavy packs of 1958, and the pack of sauerkraut was down sharply. Among other items on which information is available, the pack of green lima beans was materially larger than a year earlier and pumpkin and squash moderately larger. But packs of asparagus and cucumber pickles were down moderately, and packs of tomato catsup, paste, sauce, and pulp and puree were down substantially from the large packs of 1958.

Remaining Supplies a Little Smaller Than a Year Ago, Above Average

The smaller overall pack of canned vegetables in 1959, compared with 1958, was largely offset by substantially larger carryover stocks at the beginning of the current season. Thus, total supplies available for the current marketing year, ending in mid-1960, were near the heavy supplies of the previous season. Overall movement of canned vegetables in the first part of the season appears to have been moderately larger than in the corresponding months of last season. This, together with incomplete stocks data, indicates that remaining supplies of canned vegetables probably are a little smaller than a year ago, but at least moderately above the 1949-58 average. Among items on which recent stocks data are available, canner stocks of sweet corn were materially above the relatively low levels of a year ago. But canners' stocks of green peas were almost a fifth smaller than the heavy holdings of a year earlier, sauerkraut almost a third smaller and asparagus about a tenth smaller. Although recent stocks data are not available, remaining supplies of green lima beans, and spinach probably are larger than a year ago. Because of reduced 1959 packs, however, supplies of cucumbers for pickles probably are moderately smaller than a year ago, and supplies of tomatoes, tomato juice, and most tomato products substantially smaller. Most of these items were in very heavy supply a year ago. Except for sauerkraut, all major items appear to be in ample supply.

Movement of canned vegetables into consumption channels during the remainder of the current season is likely to be slightly larger than a year earlier. Overall stocks at the end of the current year are expected to be at least moderately smaller than the large stocks at the beginning of the season.

During the first part of the current season distributor demand was generally dull compared with canner offerings, and f.o.b. prices relatively low. In recent weeks prices of a large number of items have advanced slightly, but except for sauerkraut, pumpkin, spinach, and some tomato items, f.o.b. prices are generally below those of a year ago. Some further moderate price advances are expected into the spring. During the remainder of the season, f.o.b. prices are likely to average the same to slightly above those of last season. Retail prices are likely to average a little higher than a year earlier.

FROZEN VEGETABLES

1959 Pack Probably Near That of 1958

Pack figures for 1959 are not yet available for most frozen items, but there are indications that the total commercial pack of frozen vegetables was about the same or slightly larger than the 1,428 million pounds frozen in 1958. The 1959 pack of frozen green peas amounted to 305 million pounds, 53 million more than in 1958. The pack of cut corn at 117 million pounds was up 8 million pounds from a year earlier, and frozen asparagus at almost 33 million pounds was also up 8 million pounds. The 1959 pack of spinach probably was up substantially from a year earlier owing to the sharp increase in the important spring pack. These and other increases will be at least partly offset by expected decreases for broccoli, cauliflower, and a number of miscellaneous and mixed items.

Remaining Supplies About The Same as a Year Ago

Indications are that the overall rate of movement of frozen vegetables was moderately larger in the first half of the current season than a year earlier. Net outmovement in December amounted to almost 63 million pounds, 9 million more than in December 1958. Remaining supplies of 845 million pounds are 2 million less than a year ago, but substantially above the 1954-58 average. January 1 cold storage holdings of green peas, spinach and Brussels sprouts were materially larger than those of January 1, 1959 and sweet corn and frozen french fried potatoes slightly larger. But these increases were offset by substantially smaller stocks of asparagus, lima beans, broccoli, cauliflower, mixed peas and carrots, and mixed and "other" vegetables. Holdings of snap beans were slightly smaller than a year ago.

Prospect Next Few Months

Demand for frozen vegetables is likely to continue strong, and movement in the first half of 1960 is likely to be moderately larger than in the first half of 1959. Stocks at the end of the current season are likely to be at

least moderately below the relatively heavy holdings at the beginning of the season. Retail prices of frozen vegetables are expected to remain at moderate levels during the next 4 to 6 months, but prices of most items probably will average slightly to moderately above those of a year earlier. During the next two months, movement of frozen vegetables is likely to be stimulated by short supplies of a number of fresh items.

POTATOES

Review of 1959

Potato supplies were heavy during the winter of 1958-59, owing to large stocks of potatoes from the previous fall crop, and prices were generally low. By early spring, however, movement into food channels and heavy diversions to starch and livestock feed had reduced holdings of potatoes to moderate levels. Also, combined production of early and late spring potatoes in 1959 amounted to 26.7 million hundredweight, moderately less than either 1958 or the 1949-57 average. With these smaller supplies, prices to growers moved up sharply from $1.04 in March to $3.76 in June. As marketings from the summer crop picked up, prices declined rapidly from the high June level, but remained well above the depressed levels of a year earlier. Production of fall crop potatoes was materially below that of a year ago. Disappearance too has been somewhat smaller than in the fall of 1958. Disappearance of the 1959 fall crop to January 1 was about 68 million hundredweight, compared with almost 75 million from the larger 1958 crop. Movement to fresh market outlets probably was close to that of last fall, and movement to potato chippers and other food processors a little larger. But movement to starch factories and livestock feed was materially below 1958. Prices continue to average well above the low levels of last fall. Prices received by growers in December averaged $1.89 per hundredweight, compared with $1.17 in December 1958.

Much of Fall Crop Again Under Marketing Orders

Marketing agreement and order programs, similar to those in effect during the past several seasons, are again in effect this season in a number of major fall-producing areas. The orders impose certain size, quality, and maturity restrictions on marketing of tablestock potatoes. The regulations generally encourage more orderly marketing of better quality potatoes, and increase returns to growers. Federal marketing orders for potatoes are now in operation in Maine, the Red River Valley of Minnesota and North Dakota, Colorado, Idaho, Washington, Oregon, and the counties of Modoc and

Siskiyou in Northern California. About 70 percent of the 1959 fall crop production was in areas covered by Federal marketing orders. Except for Maine, the size and/or quality restrictions under the Federal orders are somewhat lower this season than last. Some additional areas operate under State marketing agreements and orders.

Smaller Supplies, Higher Prices In Prospect Into Early Spring

Total supplies of potatoes available for distribution into early spring are somewhat smaller than the relatively heavy supplies of a year earlier. Stocks of potatoes on hand are smaller than a year ago, and estimated production for winter harvest also is down.

Total storage stocks of potatoes held by growers and dealers in 26 fall-producing States on January 1, 1960 amounted to 97.5 million hundredweight. These stocks according to the USDA Crop Reporting Board were moderately above the 10-year average but almost 11 million hundredweight below those of January 1, 1959. Production of potatoes for 1960 winter harvest in Florida and California was estimated on January 1 at 3.5 million hundredweight, compared with 4.0 million last winter. Also, the Florida crop was damaged and yield prospects lowered by low temperatures from January 20 to 25. The winter crop of course makes up only a small part of the market requirements for the season; the bulk of winter supplies come from storage stocks.

The picture into early spring looks like one of ample but not burdensome overall supplies of potatoes. However, supplies of new crop winter potatoes are expected to be the smallest since 1952. Prices of both storage and new crop potatoes into early spring are expected to average materially above the low levels of a year earlier.

Spring Production Likely To be Moderately Larger; No Sharp Price Increase

Although no production estimates are available for the spring crops, production probably will be somewhat larger than the relatively light output of 1959. Intentions reports indicate that acreage for early spring harvest, partically all of which is in Florida, will likely be about 8 percent larger than last year. Also, yields may be above last spring, when much of the Florida crop ran to small sizes. Yields near the average of recent years on intended acreage would result in early spring production materially larger than the 1959 crop of 3.1 million hundredweight.

Intentions reports indicate that potato growers plan to plant about 6 percent more acreage for late spring harvest this year than last. On such an acreage, yields near the average of recent years would result in a production a little larger than in 1959, and probably close to the 1949-58 average. Acreage in California, which grows about 60 percent of the late spring crop, is up 13 percent from last year. However, yields may be at least moderately below the high level of 1959. Acreage is up 4 percent in Texas, but down 10 percent in Arizona. In large producing areas in the East, acreage is up 11 percent in Alabama, and up slightly in North Carolina.

If growing and harvesting conditions for the spring crop are near the average of recent years, prices to growers in early spring will likely average substantially above the early weeks of the 1959 spring season. But prices are not likely to show sharp advances similar to those of last spring. Prices of potatoes in late spring probably will average materially below the levels of a year earlier.

Foreign Trade

On an annual basis United States foreign trade in potatoes, conducted mostly with Canada, is small relative to domestic production. Exports typically amount to less than 2 percent of production, and imports less than 1 percent. Nevertheless, to certain areas and at certain times our foreign trade is important. United States exports of potatoes from July 1958 through June 1959 amounted to about 4 million hundredweight, and imports less than 1 million hundredweight.

United States exports of potatoes in the early part of the current season were below the corresponding period of last season. But with Canadian supplies materially smaller than a year ago, U. S. exports in the first half of 1960 are expected to be substantially larger than those of a year earlier. Imports into the U. S. into mid-1960 are likely to be relatively light, and to consist mainly of seed stock.

Prospects Beyond Spring

It is too early to attempt to assess the probable supply and price prospects for potatoes into summer and fall. But it is not too early for producers to begin shaping up plans for these crops. In laying their plans producers should remember that people like to eat about the same quantity of potatoes from one year to the next, regardless of price. Any substantial overproduction results in seriously depressed prices. To avoid the likelihood of burdensome supplies and low prices, producers should make at least moderate cuts in acreage of both summer and fall crop potatoes.

The U. S. Department of Agriculture Acreage-Marketing Guide for the early summer, late summer and fall crops will be released in February. Through these recommendations, an attempt is made to guide growers in adjusting production to anticipated market needs. Copies of the guides may be obtained from the Agricultural Marketing Service, USDA, Washington 25, D. C.

SWEETPOTATOES

1960 Crop Materially Larger Than Last Year

Sweetpotato production in 1959, at 18.7 million hundredweight, was moderately below the 1948-57 average, but about 8 percent above that of 1958. Acreage harvested was slightly larger than in 1958, with increases in Virginia, North Carolina, South Carolina, Georgia, Tennessee, Texas, and California. These increases more than offset declines in Maryland, Florida, Alabama, Arkansas, and Oklahoma. No change in acreage from last year was reported for New Jersey, Missouri, Kansas, Kentucky, Mississippi, and Louisiana. The season was generally favorable for sweetpotatoes and U. S. average yield of 68 hundredweight per acre was record high.

Combined production in New Jersey, Virginia, North Carolina, Louisiana, Texas and California, which furnish the bulk of shipments in the last half of the season, was 7 percent larger than last year. Unloads data indicate that so far this season marketings from these States have been a little larger than in the comparable period last season. This indicates that remaining supplies are at least moderately, and perhaps materially, larger than a year ago.

Prices Next Few Months Likely to Continue Below a Year Earlier

Demand for sweetpotatoes this season is about the same as it was last season, but this season's larger crop has kept prices under pressure. During the first half of the season total unloads in the 38 cities reporting were slightly above those of a year earlier and prices to growers averaged about 50 cents lower. Peak marketings occurred in the fall, with a seasonal low price of $2.54 per hundredweight to the grower in October. Prices to growers in December averaged $3.43 per hundredweight, but were still more than a dollar below those of mid-December 1958. The 8 percent larger crop in 1959 than in 1958, together with unloads data in the 38 cities, indicate that current holdings of sweetpotatoes are somewhat larger than holdings a year ago. Prices during the next 2 to 3 months are likely to average substantially below those of a year earlier.

DRY EDIBLE BEANS

Total Supplies Little Below Last Season; Less Colored More White

Total production of dry edible beans in 1959 was 18.2 million hundredweight, compared with 19.2 million in 1958. Stocks at the beginning of the current season were somewhat larger than a year earlier. Thus, total supplies available for distribution in the 1959-60 season were only slightly less than last season and slightly more than the 1953-57 average. Although total supplies were close to those of a year ago, distribution by classes was quite different.

Total supplies of colored beans available in the current season amounted to a little less than 7 million hundredweight, almost a fifth less than last season, and materially below average. Production of Pintos, at 4.3 million hundredweight, was about 600,000 hundredweight less than last year. As beginning stocks of this class probably were smaller than they were last season, supply was likely down more than 600,000 bags, and substantially below average. Among other important colored classes, production of both red kidney and small reds was much smaller in the 1959 season than in 1958. As a result, supply of red kidney beans is about 30 percent smaller than both last season and the recent 5-year average. Supply of small red beans in the current season was down a third from last season, and moderately below the 1953-57 average. Among the less important classes, pink beans are also in substantially smaller supply than a year ago, but supplies of cranberry beans are larger. All colored beans together make up about 36 percent of the total supplies compared with 43 percent last season and the 1953-57 average of 42 percent.

In contrast to the light supply of colored beans, total supply of white beans at the beginning of the season amounted to more than 9 million hundredweight. This was about an eighth larger than in the previous season, and a fourth above the 1953-57 average. Because of sharply higher yields in Michigan, production of pea beans, at 5.8 million hundredweight, was considerably above the 5.1 million produced in 1958. Production of great northern and small white beans was also up, and supplies of each of these were substantially larger than both last season and average. Total supply of lima beans was materially smaller than a year ago and much below average. Supplies of baby limas were about the same as last season, but because of reduced production, supplies of large limas were about an eighth smaller. Supply of blackeye beans appeared to be about the same as last season, and a tenth above average.

Disappearance Probably Will be Smaller Than Last Season

Domestic use of dry beans in the current season may be slightly above the 14.9 million hundredweight used last season. Since domestic demand for dry beans is quite inelastic, however, there is little prospect for any very sizeable increase.

Exports of dry beans from this country, greatly influenced by production in Europe, vary considerably from year to year. But in recent years there has been a growing demand for export. This trend toward increased exports is expected to continue in the years ahead. However, the very heavy exports -- 4.0 million hundredweight -- last season was due in part to a poor crop in Europe. With the 1959 crop in Central and Northern Europe reported to be hard hit by prolonged drought, and with heavy U. S. supplies of white beans, large exports in the first part of the current season resulted. Total exports of dry beans in the period September-November amounted to 1.2 million hundredweight compared with 704,000 hundredweight a

year earlier. All of the increase was in white types, as export movement of colored types was smaller than a year earlier. Exports of white beans for the season as a whole probably will be very large. However, because of tight supplies and high prices of colored beans, it seems unlikely that total exports of beans will be as large this season as last.

Price Prospects

Domestic demand for both white and colored beans was good and export movement of white classes in the early part of the season was unusually large. Colored classes are in generally tight supply and prices for the season to date have averaged materially above those of a year earlier. For example, according to the Bean Market News, Colorado shipping point prices of Pintos, largest of the colored classes, was $8.60 to $8.75 per hundredweight for the week ended January 14, compared with about $6.80 a year earlier. Red kidneys and small reds are also in light supply and prices are substantially above those of a year ago. During the next few months prices of all major colored classes are expected to remain well above those of last season.

Prices of both large and baby limas are above a year earlier. Supplies of Great Northern are significantly larger than a year ago. But demand has been strong and in recent weeks prices of northerns have moved above year earlier levels. Heavy supplies of pea beans, largest of the white classes, continue to weigh on markets. Prices for this class are expected to remain below those of a year earlier, but above support levels.

Pricing Policy for any 1959-Crop Dry Beans Taken Over Under Support

The U. S. Department of Agriculture announced that the Commodity Credit Corporation had no inventory of dry beans as of January 21, but outlined a pricing policy for any beans that might be taken over in coming weeks under the price support program.

Through December 31, 1959, a total of 1,822,066 hundredweight of 1959-crop dry beans had been put under price-support loans and purchase agreements. This is somewhat smaller than the 2,789,586 hundredweight of 1958-crop dry beans put under support through December 31,1958. Market prices have been above support prices and producers should find it profitable to redeem their beans under price-support loan prior to the maturity dates of February 29 in New York, Michigan, and Pennsylvania and April 30 in all other States.

Any 1959-crop dry beans taken over by the Commodity Credit Corporation will be sold at the higher of the domestic market price or the statutory minimum price, which is 105 percent of the 1959 support rates plus reasonable carrying charges. This pricing will apply to both domestic and export sales. Any 1959-crop beans acquired under price support and which are not sold

through commercial channels under this pricing policy will be made available, prior to the 1960 harvest, to noncommercial outlets such as domestic and foreign donation.

The pricing policy is designed to encourage maximum movement of dry beans into commercial market channels. It removes any uncertainty regarding CCC pricing of dry beans and should make commercial holding of the dry bean inventory possible.

DRY FIELD PEAS

Supplies Much Larger Than Light Supplies Of Last Season

Supplies of dry field peas are much larger than the relatively light supplies of a year ago, and probably moderately above the 1949-57 average. Stocks of dry peas at the beginning of the season, September 1, 1959, were very light and far below the relatively heavy stocks of a year earlier. But 1959 production of 4.4 million hundredweight was the second largest since 1947 and about 75 percent larger than the small 1958 crop. Biggest increase in 1959 production over 1958, occurred in Alaskas and other smooth green kinds, which were up about 90 percent. But production of white Canada and other yellow and white kinds was about two-thirds larger than in 1958, and output of "other peas," mostly wrinkled kinds, was up about 50 percent. Total production in Washington, at 2.2 million hundredweight, was double that of last season, and production in Idaho, at 1.8 million hundredweight, was up 64 percent. The larger overall crops was the result of 47 percent more harvested acreage in 1959, and record high yields.

Demand Strong, Prices Firm to Strong

Domestic use of dry field peas in the current season is likely to be materially larger than last season. Dry peas were in tight supply last season, prices were relatively high and domestic use for food was drastically curtailed. Export demand in the early part of the season has also been unusually strong. In the period September-November exports of green kinds amounted to 433,000 hundredweight compared with 329,000 a year earlier, and exports of white and yellow kinds combined amounted to 336,000 hundredweight compared with 158,000 a year earlier. Although exports for the season as a whole may be down somewhat from the high level of last season, they are expected to compare favorably with most other recent years. So far this season f.o.b. prices of smooth green and wrinkled kinds have averaged below those of a year earlier, but prices of white and yellow kinds have averaged higher. With prospects for a good rate of movement into both domestic and foreign channels, prices in the next 4 to 6 months are expected to remain firm to strong.

Smaller Crop Needed in 1960

Indications are that a smaller crop will be needed in 1960. Carryover stocks of dry peas at the beginning of next season are likely to be substantially above the very light carryover at the beginning of the current season. This together with a crop as large as in 1959 -- 4.4 million hundredweight -- probably would result in burdensome supplies in the 1960-61 season. Domestic use of dry peas for food in 1960-61 probably will be somewhere around one million hundredweight. Based on experience of recent years, another 1.5 to 1.6 million hundredweight will go into domestic nonfood uses -- feed, seed for dry and green crops, and loss. Total domestic use typically amounts to 2.5 to 2.7 million hundredweight. Thus, in years of big crops the export market assumes increased importance. Exports in the last 3 or 4 seasons have averaged much above those of earlier years, reaching 1.5 million hundredweight in the 1958-59 season. Exports are expected to remain relatively high. But unless production is cut in 1960, and barring serious crop failure in Europe, foreign markets in 1960-61 probably would not take enough peas to keep prices to growers from falling to very low levels. To forestall the likelihood of surplus supplies and low prices next season, growers in 1960 should plant substantially less acreage than in 1959.

Table 2.--Vegetables and melons for fresh market: Commercial acreage, production, and season average price per hundredweight received by farmers for principal crops, average 1949-57, annual 1958 and 1959
